

Solving DSGE models

Macro II - Fluctuations - ENSAE, 2024-2025

Pablo Winant

2025/03/12

Introduction

What is the main specificity of economic modeling?

In (macro)economics, we *model* the behaviour of economic agents by specifying:

- ▲ their objective

$$\max_{c_t} E_t \sum_{s \geq t} \beta^s U(c_s)$$

$$\max \pi_t$$

...

- ▲ their constraints (budget constraint, econ. environment...)

What is the main specificity of economic modeling?

In (macro)economics, we *model* the behaviour of economic agents by specifying:

- ▲ their objective

$$\max_{c_t} E_t \sum_{s \geq t} \beta^s U(c_s)$$

$$\max \pi_t$$

...

- ▲ their constraints (budget constraint, econ. environment...)

This has important implications:

- ▲ macro models are *forward looking*
 - rely on expectations
- ▲ macro models need to be **solved**

In many cases, there is no closed form for the solution -> we need *numerical techniques*

Dynare

- ▲ 1996: Michel Juillard created an opensource software to solve DSGE models
 - DSGE: Dynamic Stochastic General Equilibrium
 - usually solved around a steady-state
- ▲ Now about 10 contributors.
 - + power users who have contributed to the code
- ▲ It has been widely adopted:
 - early version in Gauss
 - then Matlab/Octave/Scilab
 - latest version in Julia
 - ... and Python (checkout [dyno](#) )

Dynare

Figure 1: Michel Juillard

DSGE Models in institutions

Nowadays most DSGE models built in institutions have a Dynare version (IMF/GIMF, EC/Quest, ECB/, NYFed/FRBNY)

- ▲ they are usually based on the *midsize model* from Smets & Wouters (10 equations)
- ▲ but have grown up a lot (>>100 equations)

DSGE Models in institutions

Nowadays most DSGE models built in institutions have a Dynare version (IMF/GIMF, EC/Quest, ECB/, NYFed/FRBNY)

- ▲ they are usually based on the *midsize model* from Smets & Wouters (10 equations)
- ▲ but have grown up a lot (>>100 equations)

Institutions, led by researchers are diversifying their model

- ▲ Semi-Structural Models
- ▲ Computational General Equilibrium Models
- ▲ Network Models
- ▲ Agent-based Models
- ▲ Heterogenous Agents Models

The Plan

Provide a short introduction to DSGE modeling:

- ▲ How models are solved (today)
- ▲ Small Open Economy (aka IRBC model)
- ▲ Heterogeneity
- ▲ Financial Intermediation

In passing, we'll discuss some of the trends

Solving a model

Model

A very concise representation of a model

$$\mathbb{E}_t[f(y_{t+1}, y_t, y_{t-1}, \varepsilon_t)] = 0$$

The **problem**:

- ▲ $y_t \in \mathbb{R}^n$: the vector of endogenous variables
- ▲ $\varepsilon_t \in \mathbb{R}^{n_e}$: the vector of exogenous variables
 - we assume that ε_t is a zero-mean gaussian process
- ▲ $f : \mathbb{R}^n \rightarrow \mathbb{R}^n$: the model equations

The **solution**:

- ▲ g such that

$$\forall t, y_t = g(y_{t-1}, \varepsilon_t)$$

Model

The situation is different when one is making a perfect foresight simulation.

The timing of the equations

Tip

In a dynare modefile the model equations are coded in the `model; ... ; end;` block.

Variable v_t (resp v_{t-1} , v_{t+1}) is denoted by `v` or `v(0)` (resp `v(-1)`, `v(+1)`).

General Timing Convention

New information arrives with the innovations ε_t .

At date t , the information set is spanned by $\mathcal{F}_t = \mathcal{F}(\dots, \varepsilon_{t-3}, \varepsilon_{t-2}, \varepsilon_{t-1}, \varepsilon_t)$

By convention *an endogenous variable has a subscript t if it is known first at date t .*

The timing of the equations

The timing of the equations

Tip

In a dynare modefile the model equations are coded in the `model; ... ; end;` block.

Variable v_t (resp v_{t-1} , v_{t+1}) is denoted by `v` or `v(0)` (resp `v(-1)`, `v(+1)`).

General Timing Convention

New information arrives with the innovations ε_t .

At date t , the information set is spanned by $\mathcal{F}_t = \mathcal{F}(\dots, \varepsilon_{t-3}, \varepsilon_{t-2}, \varepsilon_{t-1}, \varepsilon_t)$

By convention *an endogenous variable has a subscript t if it is known first at date t .*

Several **variable types** depending on how they appear in the model:

- ▲ jump variable: appear t or $t + 1$
- ▲ predetermined variable: appear in $t - 1$ and t (possibly $t + 1$)

The timing of the equations

- ▲ static variables: appear in t only
 - can be expressed as a function of other variables

The timing of equations

Example

Using Dynare's timing conventions:

- ▲ Write the production function in the RBC
- ▲ Write the law of motion for capital k , with a depreciation rate δ and investment i
 - when is capital known?
 - when is investment known?
- ▲ Add a multiplicative investment efficiency shock χ_t . Assume it is an **AR(1)** driven by innovation η_t and autocorrelation ρ_χ
 - how do you write the law of motion for capital?

Steady-state

The deterministic steady-state satisfies:

$$f(\bar{y}, \bar{y}, \bar{y}, 0) = 0$$

Often, there is a closed-form solution.

Otherwise, one must resort to a numerical solver to solve

$$\bar{y} \rightarrow f(\bar{y}, \bar{y}, \bar{y}, 0)$$

Tip

In dynare the steady-state values are provided in the `steadystate_model; ... ; end;` block. One can check they are correct using the `check;` statement.

To find numerically the steady-state: `steady;`.

The implicit system

Replacing the solution

$$y_t = g(y_{t-1}, \varepsilon_t)$$

in the system

$$\mathbb{E}_t[f(y_{t+1}, y_t, y_{t-1}, \varepsilon_t)] = 0$$

we obtain:

$$\mathbb{E}_t[f(g(g(y_{t-1}, \varepsilon_t), \varepsilon_{t+1}), g(y_{t-1}, \varepsilon_t), y_{t-1}, \varepsilon_t)] = 0$$

It is an equation defining implicitly the function $g()$

The state-space

$$\mathbb{E}_t[f(g(g(y_{t-1}, \varepsilon_t), \varepsilon_{t+1}), g(y_{t-1}, \varepsilon_t), y_{t-1}, \varepsilon_t))] = 0$$

In this expression, y_{t-1}, ε_t is the state-space:

- ▲ it contains all information available at t to predict the future evolution of $(y_s)_{s \geq t}$

The state-space

$$\mathbb{E}_t[f(g(g(y_{t-1}, \varepsilon_t), \varepsilon_{t+1}), g(y_{t-1}, \varepsilon_t), y_{t-1}, \varepsilon_t))] = 0$$

In this expression, y_{t-1}, ε_t is the state-space:

- ▲ it contains all information available at t to predict the future evolution of $(y_s)_{s \geq t}$

Dropping the time subscripts, the equation must be satisfied for any realization of (y, ε)

$$\forall (y, \varepsilon) \text{ mid } \Phi(g)(y, \varepsilon) = \mathbb{E}_{\varepsilon'}[f(g(g(y, \varepsilon), \varepsilon'), g(y, \varepsilon), y, \varepsilon))] = 0$$

It is a functional equation $\Phi(g) = 0$

Expected shocks

First order approximation:

- ▲ Assume $|\varepsilon| \ll 1, |\varepsilon'| \ll 1$

Perform a Taylor expansion with respect to future shock:

Expected shocks

First order approximation:

- ▲ Assume $|\varepsilon| \ll 1, |\varepsilon'| \ll 1$

Perform a Taylor expansion with respect to future shock:

This uses the fact that $\mathbb{E}[\varepsilon'] = 0$.

At first order, expected shocks play no role.

To capture precautionary behaviour (like risk premia), we would need to increase the approximation order.

First order perturbation

We are left with the system:

$$F(y, \varepsilon) = f(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

A variant of the *implicit function theorem* then yields the existence of a first approximation of g :

$$g(y, \varepsilon) = \bar{y} + g'_y(y - \bar{y}) + g'_e \varepsilon_t$$

First order perturbation

We are left with the system:

$$F(y, \varepsilon) = f(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

A variant of the *implicit function theorem* then yields the existence of a first approximation of g :

$$g(y, \varepsilon) = \bar{y} + g'_y(y - \bar{y}) + g'_\varepsilon \varepsilon$$

Unknown quantities g'_y , and g'_ε are obtained using the *method of undetermined coefficients*.

Plug the first approximation into the system and write the conditions

$$F'_y(\bar{y}, 0) = 0$$

$$F'_\varepsilon(\bar{y}, 0) = 0$$

Computing g'_y

Recall the system:

$$F(y, \varepsilon) = f(g(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

We have

$$F'_y(\bar{y}, 0) = f'_{y_{t+1}} g'_y g'_y + f'_{y_t} g'_y + f'_{y_{t-1}} = 0$$

Computing g'_y

Recall the system:

$$F(y, \varepsilon) = f(g(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

We have

$$F'_y(\bar{y}, 0) = f'_{y_{t+1}} g'_y g'_y + f'_{y_t} g'_y + f'_{y_{t-1}} = 0$$

g'_y is the solution of a specific Riccati equation

$$AX^2 + BX + C$$

where A, B, C and $X = g'_y$ are square matrices $\in \mathbb{R}^n \times \mathbb{R}^n$

First Order Deterministic Model

Let's pause a minute to observe the first order deterministic model:

$$AX^2 + BX + C$$

From our intuition in dimension 1, we know there must be multiple solutions

- ▲ how do we find them?
- ▲ how do we select the right ones?

In the absence of shocks the dynamics of the model are given by

$$y_t = Xy_{t-1}$$

What is the condition for the model to be stationary?

First Order Deterministic Model

Let's pause a minute to observe the first order deterministic model:

$$AX^2 + BX + C$$

From our intuition in dimension 1, we know there must be multiple solutions

- ▲ how do we find them?
- ▲ how do we select the right ones?

In the absence of shocks the dynamics of the model are given by

$$y_t = Xy_{t-1}$$

What is the condition for the model to be stationary?

-> the biggest eigenvalue of X should be smaller than 1

Develop intuition in dimension 1.

Multiplicity of solution

It is possible to show that the system is associated with $2n$ generalized eigenvalues:

$$|\lambda_1| \leq \dots \leq |\lambda_{2n}|$$

For each choice C of n eigenvalues ($|C| = n$), a specific recursive solution X_C can be *constructed*. It has eigenvalues C .

Multiplicity of solution

It is possible to show that the system is associated with $2n$ generalized eigenvalues:

$$|\lambda_1| \leq \dots \leq |\lambda_{2n}|$$

For each choice C of n eigenvalues ($|C| = n$), a specific recursive solution X_C can be *constructed*. It has eigenvalues C .

This yields at least $\binom{2n}{n}$ different combinations.

Multiplicity of solution

It is possible to show that the system is associated with $2n$ generalized eigenvalues:

$$|\lambda_1| \leq \dots \leq |\lambda_{2n}|$$

For each choice C of n eigenvalues ($|C| = n$), a specific recursive solution X_C can be *constructed*. It has eigenvalues C .

This yields at least $\binom{2n}{n}$ different combinations.

A model is well defined when there is **exactly one solution that is non divergent**.

This is equivalent to:

$$|\lambda_1| \leq \dots \leq |\lambda_n| \leq 1 < |\lambda_{n+1}| \leq \dots \leq |\lambda_{2n}|$$

Example 1

Forward looking inflation:

$$\pi_t = \alpha \pi_{t+1}$$

with $\alpha < 1$.

Is it well defined?

Example 1

Example 1

Forward looking inflation:

$$\pi_t = \alpha \pi_{t+1}$$

with $\alpha < 1$.

Is it well defined?

We can rewrite the system as:

$$\alpha \pi_{t+1} - \pi_t + 0 \pi_{t-1} = 0$$

or

$$\pi_{t+1} - \left(\frac{1}{\alpha} + 0\right) \pi_t + \left(\frac{1}{\alpha} 0\right) \pi_{t-1} = 0$$

Example 1

Example 1

Forward looking inflation:

$$\pi_t = \alpha \pi_{t+1}$$

with $\alpha < 1$.

Is it well defined?

We can rewrite the system as:

$$\alpha \pi_{t+1} - \pi_t + 0 \pi_{t-1} = 0$$

or

$$\pi_{t+1} - \left(\frac{1}{\alpha} + 0\right) \pi_t + \left(\frac{1}{\alpha} 0\right) \pi_{t-1} = 0$$

The generalized eigenvalues are $0 \leq 1 < \frac{1}{\alpha}$.

Example 1

Example 1

Forward looking inflation:

$$\pi_t = \alpha \pi_{t+1}$$

with $\alpha < 1$.

Is it well defined?

We can rewrite the system as:

$$\alpha \pi_{t+1} - \pi_t + 0 \pi_{t-1} = 0$$

or

$$\pi_{t+1} - \left(\frac{1}{\alpha} + 0\right) \pi_t + \left(\frac{1}{\alpha} 0\right) \pi_{t-1} = 0$$

The generalized eigenvalues are $0 \leq 1 < \frac{1}{\alpha}$.

Example 1

The unique stable solution is $\pi_t = 0\pi_{t-1}$

Example 2

Debt accumulation equation by a rational agent:

$$b_{t+1} - \left(1 + \frac{1}{\beta}\right)b_t + \frac{1}{\beta}b_{t-1} = 0$$

Is it well-defined?

Example 2

Debt accumulation equation by a rational agent:

$$b_{t+1} - \left(1 + \frac{1}{\beta}\right)b_t + \frac{1}{\beta}b_{t-1} = 0$$

Is it well-defined?

Two generalized eigenvalues $\lambda_1 = 1 < \lambda_2 = \frac{1}{\beta}$

Example 2

Debt accumulation equation by a rational agent:

$$b_{t+1} - \left(1 + \frac{1}{\beta}\right)b_t + \frac{1}{\beta}b_{t-1} = 0$$

Is it well-defined?

Two generalized eigenvalues $\lambda_1 = 1 < \lambda_2 = \frac{1}{\beta}$

The unique non-diverging solution is $b_t = b_{t-1}$.

- ▲ it is a *unit-root*: any initial deviation in b_{t-1} has persistent effects

Example 3

Productivity process:

$$z_t = \rho z_{t-1}$$

with $\rho < 1$: well defined

Example 3

Example 3

Productivity process:

$$z_t = \rho z_{t-1}$$

with $\rho < 1$: well defined

In that case there is a hidden infinite eigenvalue ∞ associated to z_{t+1} .

Example 3

Example 3

Productivity process:

$$z_t = \rho z_{t-1}$$

with $\rho < 1$: well defined

In that case there is a hidden infinite eigenvalue ∞ associated to z_{t+1} .

To see why consider the system associated with eigenvalues m and ρ :

$$z_{t+1} - (m + \rho)z_t + m\rho z_{t-1} = 0$$

$$\frac{1}{m}z_{t+1} - \left(1 + \frac{\rho}{m}\right)z_t + \rho z_{t-1} = 0$$

Which corresponds to the initial model when $m = \infty$

Example 3

Example 3

Productivity process:

$$z_t = \rho z_{t-1}$$

with $\rho < 1$: well defined

In that case there is a hidden infinite eigenvalue ∞ associated to z_{t+1} .

To see why consider the system associated with eigenvalues m and ρ :

$$z_{t+1} - (m + \rho)z_t + m\rho z_{t-1} = 0$$

$$\frac{1}{m}z_{t+1} - \left(1 + \frac{\rho}{m}\right)z_t + \rho z_{t-1} = 0$$

Which corresponds to the initial model when $m = \infty$

The generalized eigenvalues are $\lambda_1 = \rho \leq 1 < \lambda_2 = \infty$

Example 3

More generally, any variable that does not appear in $t + 1$ creates one infinite generalized eigenvalue.

A criterium for well-definedness

Looking again at the list of eigenvalues we set aside the infinite ones.

The model is well specified iff we can sort the eigenvalues as:

$$|\lambda_1| \leq \dots \leq |\lambda_n| \leq 1 < |\lambda_{n+1}| \leq \dots |\lambda_{n+k}| \leq \underbrace{|\lambda_{n+k+1}| \dots \leq |\lambda_{2n}|}_{\text{infinite eigenvalues}}$$

77 Blanchard-Kahn criterium

The model satisfies the Blanchard-Kahn criterium if the number of eigenvalues greater than one, is exactly equal to the number of variables *appearing* in $t + 1$.

In that case the model is well-defined.

Computing the solution

There are several classical methods to compute the solution to the algebraic Riccati equation:

$$AX^2 + BX + C = 0$$

- ▲ qz decomposition
 - traditionnally used in the DSGE literature since Chris Sims
 - a little bit unintuitive
- ▲ cyclic reduction
 - new default in dynare, more adequate for big models
- ▲ linear time iteration (see section “Linear time iteration”)
 - conceptually very simple

Computing g'_e

Now we have g'_y , how do we get g'_e ?

Recall:

$$F(y, \varepsilon) = f(g(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

We have

$$F'_e(\bar{y}, 0) = f'_{y_{t+1}} g'_y g'_e + f'_{y_t} g'_e + f'_{\varepsilon_t} = 0$$

Now this is easy:

$$g'_e = -\left(f'_{y_{t+1}} g'_y + f'_{y_t}\right)^{-1} f'_{\varepsilon_t} = 0$$

The model solution

The result of the model solution:

$$y_t = g_y y_{t-1} + g_e \varepsilon_t$$

It is an AR(1), driven by exogenous shock ε_t .

The model solution

The model solution

The result of the model solution:

$$y_t = g_y y_{t-1} + g_e \varepsilon_t$$

It is an AR(1), driven by exogenous shock ε_t .

Because it is a well known structure, one can investigate the model with

- ▲ impulse response functions
- ▲ stochastic simulations

The model solution

The model solution

The result of the model solution:

$$y_t = g_y y_{t-1} + g_e \varepsilon_t$$

It is an AR(1), driven by exogenous shock ε_t .

Because it is a well known structure, one can investigate the model with

- ▲ impulse response functions
- ▲ stochastic simulations

Then to compare the model to the data we compute

- ▲ implied moments:
 - covariances, autocorrelation
- ▲ likelihood

The model solution

Optimizing the fit to the data is called *model* estimation

Conclusion

What can you do with the solution

The solution of a model found by Dynare has an especially simple form: an AR(1)

- ▲ $y_t = Xy_{t-1} + Y\varepsilon_t$
- ▲ where the covariances Σ of ε_t can be chosen by the modeler

What can you do with the solution

The solution of a model found by Dynare has an especially simple form: an AR(1)

- ▲ $y_t = Xy_{t-1} + Y\varepsilon_t$
- ▲ where the covariances Σ of ε_t can be chosen by the modeler

With this solution we can (cf next TD)

- ▲ compute (conditional and unconditional) moments
- ▲ perform stochastic simulations, impulse response function

What can you do with the solution

The solution of a model found by Dynare has an especially simple form: an AR(1)

- ▲ $y_t = Xy_{t-1} + Y\varepsilon_t$
- ▲ where the covariances Σ of ε_t can be chosen by the modeler

With this solution we can (cf next TD)

- ▲ compute (conditional and unconditional) moments
- ▲ perform stochastic simulations, impulse response function

Going Further

Taking the model to the data with Dynare

- ▲ “estimate” the model: compute the likelihood of a solution and maximize it by choosing the right parameters
- ▲ “identify” shocks in the data

Other functions

- ▲ higher order approximation
- ▲ (nonlinear) perfect foresight simulations
- ▲ ramsey plan
- ▲ discretionary policy
- ▲ ...

Appendix: Linear Time Iteration

Linear Time Iteration

Recall the system to solve:

$$F(y, \varepsilon) = f(g(g(y, \varepsilon), 0), g(y, \varepsilon), y, \varepsilon) = 0$$

but now assume the decision rules today and tomorrow are different:

- ▲ today: $y_t = g(y_{t-1}, \varepsilon_t) = \bar{y} + Xy_{t-1} + g_y \varepsilon_t$
- ▲ tomorrow: $y_{t+1} = \tilde{g}(y_t, \varepsilon_{t+1}) = \bar{y} + \tilde{X}y_{t-1} + \tilde{g}_y \varepsilon_t$

Then the Ricatti equation is written:

$$A\tilde{X}X + BX + C = 0$$

Linear Time Iteration (2)

The linear time iteration algorithm consists in solving the decision rule X today as a function of decision rule tomorrow \tilde{X} .

This corresponds to the simple formula:

$$X = -(A\tilde{X} + B)^{-1}C$$

And the full algorithm can be described as:

- ▲ choose X_0
- ▲ for any X_n , compute $X_{n+1} = T(X_n) = -(AX_n + B)^{-1}C$
 - repeat until convergence

Linear Time Iteration (3)

It can be shown that, starting from a random initial guess, the linear time-iteration algorithm converges to the solution X with the smallest modulus:

$$\underbrace{|\lambda_1| \leq \dots \leq |\lambda_n|}_{\text{Selected eigenvalues}} \leq |\lambda_{n+1}| \dots \leq |\lambda_{2n}|$$

In other words, it finds the right solution when the model is well specified.

How do you check it is well specified?

- ▲ λ_n is the biggest eigenvalue of solution X
- ▲ what about λ_{n+1} ?
 - $\frac{1}{\lambda_{n+1}}$ is the biggest eigenvalue of $(AX + B)^{-1}A$

Linear Time Iteration (4)

Define

$$M(\lambda) = A\lambda^2 + B\lambda + C$$

For any solution X , $M(\lambda)$ can be factorized as:¹

$$M(\lambda) = (\lambda A + AX + B)(\lambda I - X)$$

and

$$\det(M(\lambda)) = \underbrace{\det(\lambda A + AX + B)}_{Q(\lambda)} \det(\lambda I - X)$$

¹Special case of Bezout theorem. Easy to check in that case

Linear Time Iteration (4)

By construction $Q(\lambda)$ is a polynomial whose roots are those that are not selected by the solution,
 Λ
i.e. $\text{Sp}(X)$.

Linear Time Iteration (5)

For $\lambda \neq 0$ we have:

$$\lambda \in \text{Sp}((AX + B)^{-1}A)$$

$$\Leftrightarrow \det((AX + B)^{-1}A - I\lambda) = 0$$

$$\Leftrightarrow \det\left(\frac{1}{\lambda}A - I(AX + B)\right) = 0$$

$$\Leftrightarrow Q\left(\frac{1}{\lambda}\right) = 0$$

$$\Leftrightarrow \frac{1}{\lambda} \in \Lambda$$

$$\text{Sp}(X)$$

Linear Time Iteration (5)

In words, $(AX + B)^{-1}$ contains all the eigenvalues that have been rejected by the selection of X .

In particular, $\rho((AX + B)^{-1}A) = \frac{1}{\min(\Lambda_{\text{Sp}(X)})}$.
